Recorder	Records decisions	
Reporter	Reports to class	
Reflector	Assesses team performance	

### The Counter Example

Consider the following Python code and discuss the questions below. The code is in the `examples-state` branch of the `release` repository.

```
1 def mkInc(start=0):
2     i = start
3     def doit(ignore=0): -- for something later
4         nonlocal i
5         i = i + 1
6         return i
7
8     return doit
9
10 c1 = mkInc(0)
11 c2 = mkInc(10)
```

**Problem 1)** What is the scope of `i` in the `mkInc` function?

**Problem 2)** If we call `c1()`, it returns 1. If we call it again, it returns 2. If we then call `c2()`, we get 11. The variables `i` that were created in `mkInc` seem to be persistent. How does that happen?

# The Delay Class

Here is a very special class. If you aren't familiar with Python, the `__init__` method is the constructor, and all methods have an initial argument `self` that refers to the current object. The `format` function replaces the `{}` in a string with its argument.

```
1 class Delay:
2     def __init__(self, action):
3         self.action = action
4         self.status = 0
5
6     def report(x):
7         print("Thunk executed: {}".format(x))
8         return x
9
10    def force(self):
11        if self.status == 2:
12            return self.value
13        elif self.status == 0:
14            self.status = 1
15            self.value = Delay.report(self.action())
16            self.status = 2
17            return self.value
18        else:
19            return Exception("It broke!")
```

**Problem 3)** Python has dynamic typing, but what is the expected type of `action`?

**Problem 4)** The `status` variable has three possible values: 0, 1, and 2. What do they mean?

**Problem 5)** What do you think this code will print?

```
1 def plus(a,b,c):
2     return a.force() + b.force()
3
4 d1 = Delay(lambda: 1+1)
5 d2 = Delay(lambda: 2+2)
6 d3 = Delay(lambda: 3+3)
7 plus(d1,d2,d3)
8 plus(d1,d2,d3)
```

# Lazy Lists

Consider this function and list definition.

```
1 def lazyTake(n,x):
2     if x==() or n<1:
3         return ()
4     else:
5         return (x[0],lazyTake(n-1,x[1].force()))
6
7 l1 = (2,Delay(lambda: (3, Delay(lambda: (5, Delay(lambda: ()))))))
8 ones = (1,Delay(lambda: ones))
```

**Problem 6)** How does this code implement lists? Note there are lazy lists and eager lists represented here.

**Problem 7)** How does that definition of ones work? Python normally does not allow recursive definitions...

**Problem 8)** Using this technique, write lazyTail and lazyMap

**Problem 9)** Write `lazyZipWith`.

**Problem 10)** Use these functions to make the infinite list of natural numbers `nats` and Fibonacci numbers `fib`.
